ABSTRACT

Volume III-B contains appendices to the analytic report in Volume III-A of the five-volume study. In Appendix A three basic indices of segregation used in the study are described as functions of several independent variables and are defined by assigning definite values to those variables. Appendix B provides projection formulas used for estimating universe totals, worst case standard errors, estimates of average value of the indices of segregation, and the standard deviation of the estimator. Tables show standard deviation estimates of average indices of segregation as percentages of projected values for all schools, elementary schools, and secondary schools. Appendix C provides: (1) the estimated number of Hispanic students in all public schools in the universe and in the regions, by characteristics of school district; (2) the estimated average values of the indices of segregation in all public schools, elementary schools, and secondary schools in the universe and the regions, by characteristics of school district; (3) the average per district change in the values of the indices of segregation for districts in the matched sample by pattern of change; and (4) detailed listings of the values of the indices of segregation and changes in the values for the districts in the matched sample. APPENDICES A - C

VOL. III

APPENDIX A. INDICES OF SEGREGATION

This appendix describes all indices of segregation considered for use in this study. Three basic types of indices were used:

- Isolation Index (E): The proportion of students of one racial group exposed to "high" concentrations of students of other racial groups.
- R Index (R): A standardized measure of the extent to which the average student of one racial group is exposed to members of another racial group.
- Dissimilarity Index (D): A measure of the extent to which the racial composition of schools deviated from a "model" racial composition for schools in a district.

Each of these indices is dependent upon the racial groups being examined. Moreover, each index can be defined as a function of several independent variables. For instance, the value of the Isolation Index is dependent upon the level used to define "high" concentrations. Consequently, a new index of segregation is defined whenever these independent variables are changed. The indices are also dependent upon the school level being considered (elementary, secondary, and all schools).

A total of 24 indices were computed with preliminary data for this study. After their distributions and intercorrelations were examined and their conceptual utility considered, ten were selected for use in the study.

In the following discussion, each of the indices is described as a function of several independent variables. The precise indices are then defined by assigning definite values to the independent variables.

The following notation is used in this presentation:

X_s = Value of the variable X at a school

$\sum_s X_s$ = Sum of the variable X for a group of schools

X_d = Value of variable X for district d (equals $\sum_s X_s$)

$\sum_s X_d$ = Summation of variable X for each district d in a group of districts (e.g., nation)

In this description, notation of X is used to represent any variable. When several variables were used for computation of an index, a distinct letter was assigned to each variable. The meaning of the letter is defined in context.

Isolation Index (E)

The isolation Index indicates the proportion of students of one racial category attending schools of specified proportions of other students. This index is similar to those used by many researchers before 1970 and still often used by Government agencies.

The E index is a function of three independent variables:

X = The racial group(s) for which the index is computed;

Y = The racial group(s) for which concentrations are measured; and

Z = The lower bound for "high" concentrations of racial group Y.

This index is computed by determining the contribution of each school to the overall index. The contribution of a school (Cs) is defined as:

$$C_s(X,Y,Z) = \begin{cases} 0, \text{ if } & \frac{Y_s}{T_s} \leq Z \\ X_s, \text{ if } & \frac{Y_s}{T_s} \geq Z \end{cases}$$

where X, Y, and Z are as defined and T is the total enrollment at a school (note: $T_s \geq X_s + Y_s$).

The E index is computed by aggregating the contribution of each school in a group and dividing by the total aggregate enrollment of racial group X:

$$E(X,Y,Z) = \frac{\sum_s C_s (X,Y,Z)}{\sum_s X_s}$$

Hence, this index is the proportion of students of racial group X enrolled in a given group of schools who are exposed to a high concentration (greater than or equal to Z) of students in racial group Y.

This index was computed for two racial groups (X = Hispano and X = Black), for exposure to two concentrations (Z = 50% and Z = 80%) of three racial groups (Y = Hispano, Y = total minority, and Y = blacks) in three groups of schools (elementary, secondary and all).

The average value for a group of districts ($\hat{E}$) is computed as the weighted average where the weighting factor is the number of students in racial groups X:

$$\hat{E}(X,Y,Z) = \frac{\sum_d X_d E(X,Y,Z)}{\sum_d X_d}$$

where X_d is the aggregate value of X for schools in the district. In this form, the average value is the proportion of students of racial group X in the group of districts who are in a school composed of Z% or more of racial group Y.

The following two E indices were used in the analyses in this study:

E(H,M,50%): The proportion of all Hispanic students, in a group of schools, who are enrolled in schools of 50% or greater minority composition.

E(B,M,50%): The proportion of all black students, in a group of schools, who are enrolled in schools of 50% or greater minority composition.

R Index of Segregation (R)

The Segregation Index is similar to several indices used during the 1970s (e.g., Cissin's S, Pugh's desegregation index, and Coleman's R). It indicates the extent to which two racial groups are mixed at schools relative to the maximum feasible intermixture.

A direct measure of integration (S) is the extent to which two racial groups are exposed to each other. This measure for racial group X is defined as the proportion of racial group Y in the school of the average student of racial group X:

$$S(X,Y) = \frac{\sum_s \frac{X_s Y_s}{T_s}}{\sum_s X_s}$$

of the proportion of racial group Y in school with the average child of racial group X.

R is the standardized (or normalized) form of the S measure defined above. Standardization is defined such that a zero value is obtained if there is no apparent correlation between assignment of racial groups X and Y to schools (that is, if there is no apparent segregation of the two racial groups). A positive value occurs if racial group X is segregated from racial group Y.

Negative values for these indices can occur. All negative values indicate a desegregated school system and were treated as zero in this study. However, since negative values were computed and are stored on the data tapes used for this study, the precise method for standardization is described below.

Two domains are established for standardization:

- When there is segregation, or $S(X,Y) \leq \frac{\sum_s Y_s}{\sum_s T_s}$

- When there is no segregation, or $S(X,Y) > \frac{\sum_s Y_s}{\sum_s T_s}$

Standardization When There is Segregation When there is segregation, the average student of racial group X is exposed to a loser proportion of racial group Y than in the district at large. To standardize in this domain, the following formula was used·

$$R(X,Y) = \frac{\frac{\sum_s Y_s}{\sum_s T_s} - S(X,Y)}{1 - \frac{\sum_s Y_s}{\sum_s T_s}} \quad \text{whenever } S(X,Y) > \frac{\sum_s Y_s}{\sum_s T_s}$$

Note that this measure assumes a value of +1 when S(X,Y)= 0 or no students of racial group X are in school with students of racial group Y and vice-versa.

Standardization when there is no segregation. When there is no segregation, the average student of racial group X is exposed to a higher percentage of racial group Y than in the district at large.

To standardize this domain, the following formula was used:

$$R(X,Y) = \frac{\frac{\sum_s Y_s}{\sum_s T_s} - S(X,Y)}{1 - \frac{\sum_s Y_s}{\sum_s T_s}} \quad \text{whenever } S(X,Y) > \frac{\sum_s Y_s}{\sum_s T_s}$$

Note that this measure assumes the value of -1 when S(X,Y) = 1.0 or when the average student of racial group X is exposed to a school environment that is 100% of racial group Y. Negative values for the indices were computed. All analyses treated negative values as zero, which indicates no segregation.

The Segregation Index was computed for two racial groups (X = Hispano and X = black). For Hispanos, R is computed for integration with three racial groups (Y = whites, Y = non-Hispanos, and Y = blacks). Similarly, for blacks, R is computed for integration with three racial groups (Y = whites, Y = non-blacks, and Y = Hispanos).

The average value of $\hat{R}$ is the weighted average when the number of students of racial group X is used as the weighting factor. Hence, the average value is defined as:

$$\hat{R}(X,Y) = \frac{\sum_d X_c \, R(X,Y)}{\sum_d X_d}$$

This weighting places most emphasis on districts having the largest number of students of racial group X. It is the weighted average of the extent of "within-district" segregation and not the weighted average of the exposure of two racial groups to each other.

The following six R indices were used in our analyses:

R(H,W): Standardized form of S(H,W) -- The proportion of white students to which the average Hispanic student in a group of schools is exposed.

R(H,NH): Standardized form of S(H,NH) -- The proportion of non-Hispanic students to which the average Hispanic student in a group of schools is exposed.

R(H,B): Standardized form of S(H,B) -- The proportion of black students to which the average Hispanic student in a group of schools is exposed.

R(B,W): Standardized form of S(B,W) -- The proportion of white students to which the average black student in a group of schools is exposed.

R(B,NB): Standardized form of S(B,NB) -- The proportion of non-black students to which the average black student in a group of schools is exposed.

R(B,H): Standardized form of S(B,H) -- The proportion of Hispanic students to which the average black student in a group of schools is exposed.

Dissimilarity Index (D)

The Dissimilarity Index is a function of two independent variables:

X -- The racial group for which the index is computed, and

Y -- The racial group used to define the "model" for assignment of students to schools.

This index is computed by summing the absolute value of deviation from the model assignment to schools, or:

$$D(X,Y) = 1/2 \sum_s \left| \frac{Y_s}{\sum_s Y_s} - \frac{X_s}{\sum_s X_s} \right|$$

In this form, the Dissimilarity Index is the proportion of students of racial group X (and Y) who would require reassignment between schools to achieve the model distribution of students in all schools. The model distribution is essentially a desegregation goal expressed as a desired proportion of racial group Y for each school.

The Dissimilarity Index is computed for two racial groups (X = Hispano and X = blacks). For Hispanos, three different models of assignment were used.

- a "white is right" model (Y = white),
- a "non-Hispano is right" model (Y = non-Hispano), and
- a "random assignment is right" model (Y = total students).

Similarly, for blacks, three different models of assignment are used:

- a "white is right" model (Y = white)
- a "non-black is right" model (Y = non-black), and
- a "random assignment is right" model (Y = total students).

The model labeled "random assignment" is equivalent to assuming that students are assigned to schools on the basis of the size of the school alone.

The average value for a group of districts is the weighted average, using the number of students of racial groups X in the district as the weight:

$$\hat{D}(X,Y) = \frac{\sum_d X_d \, d(X,Y)}{\sum_d X_d}$$

In this form, the average dissimilarity is the proportion of students in racial group X who would be reassigned to different schools within each district to achieve the model for each district.

The following two D indices were used in these analyses:

D(H,T): The proportion of all Hispanic students in a group of schools who would be reassigned to achieve Hispanic representation at each school identical to that which would be achieved from random assignment of students to schools without altering the total enrollment of each school.

D(B,T): The proportion of all black students in a group of schools who would be reassigned to achieve black representation at each school identical to that which would be achieved from random assignment of students to schools without altering the total enrollment of each school.

APPENDIX B. PROJECTIONS AND STANDARD ERRORS

Projection Formula

Projection of Universe Totals

The projection formula used for estimating universe totals is a generalization of projection formulas for simple random samples when weighted samples are used. The universe total for a parameter (P) is estimated by multiplying the sample value P_d for the Dth district by the sampling weight (W_d) for the district (the inverse of the probability with which the district was selected for inclusion in the sample) and summing across districts ($\sum_d$):

$$P = \sum_d W_d P_d$$

The worst case standard error of the estimate is given by the square root of the sampling variance, defined as:

$$Var(P) = \sum_d W_d(W_d-1)P_d^2$$

Estimates of Averages

Ratio estimates are used for estimating average values of the indices of segregation. Given the value of index I_d for the Dth district with weight W_d which enrolls X_d students of the racial group to which the index applies, the estimate of the average value of the index is:

$$\hat{I} = \frac{Num}{Den} = \frac{\sum_d W_d X_d I_d}{\sum_d W_d X_d}$$

where 'Num' is the numerator of the estimator and 'Den,' the denominator of the estimator. The standard deviation of this estimator is given by the square root of the variance, defined as:

$$Var(\hat{I}) = \frac{1}{Den^2}\left[Var(Num) + \frac{Num^2}{Den^2}\ Var\ (Den) - 2\ \frac{Num}{Den}\ Cov(Num, Den)\right]$$

The variance of Num and Den are given by variance equations for projection of universe totals, as follows:

$$\text{Var(Num)} = W_d W_d (W_d - 1)\, X_d^2\, I_d^2$$

and

$$\text{Var(Den)} = \sum_d W_d (W_d - 1)\, X_d^2$$

Since we calculated only the worst case estimates of $\text{Var}(\hat{I})$. This was done by: $\text{Var}(\hat{I}) = \frac{1}{\text{Den}^2}\left[\text{Var(Num)} + \frac{\text{Num}^2}{\text{Den}^2}\ \text{Var (Den)}\right]$. It is generally positively correlated with X_d, the numerator and denominator of the estimator are generally positively correlated and thus our estimated variances are generally greater than the actual variances.

The tables that follow show the standard deviation estimates of average indices of segregation as percentages of the projected values. Tables B.1 through B.5 give percentages for all schools, tables B.6 to B.10 for elementary schools, and tables B.11 to B.15 for secondary schools. As anticipated, projections for 1976 show the greatest percent standard error. Nonetheless, estimates of the national average have a worse case standard deviation of less than 3%. Estimates of the averages for regions may be better or worse than the national average. With the exception of the Midwest, standard deviation is less than 5%, and in most cases are close to 2%. In the Midwest, standard deviation for one index--R(H,W)--exceeds 10%. (The Midwest shows extremely low values for this index in 1976, which contributes to the large percentage standard deviation). As indicated, these standard deviations have not been corrected for the covariance of numerator and denominator. Hence, they are maximum values; correction for the covariance would generally reduce the value.

TABLE

APPENDIX C. ADDITIONAL TABLES AND LISTINGS

The tables and listings given in this appendix provide the following information:

- Estimated number of Hispanic students in all public schools in the universe and in the regions, by characteristics of a school district.
- Estimated average values of the five indices of segregation in all public schools, elementary schools, and secondary schools in the universe and the regions, by characteristics of a school district.
- Average per district change in the values of the five indices of segregation for districts in the matched sample (sample V), by pattern of change.
- Detailed listings of the values of the indices of segregation and changes in the values for the districts in the matched sample.

The characteristics of the district (termed "independent variables" on these tables) are percent Hispanic, percent black, total enrollment, metropolitan status, and compliance code. For the first two characteristics, the values are given by level (or percentage) of enrollment: Low level = 0-9.999%; medium level = 10.0-39.999%, and high level = 40.0 - 100% Hispanic students--or black students--in the district.

Values of indices by the third characteristic--total enrollment--are given by level of enrollment (numbers of students) in the district: small districts were those enrolling 3,000-4,999 students; medium districts, 5,000 to 14,999 students; large districts, 15,000 students and above; and all districts, 3,000-999,999,999 students.

Further information needed to interpret the tables is given on the pages dividing each section of tables.

Table C.80

Tables C.81 - C.110

Average per district change in the values of the indexes of segregation in the matched sample (sample V), by pattern of change.

These tables summarize the changes in values of the indexes of segregation for districts in the matched sample. The summary is provided for each index of segregation in each region by pattern of change. In addition, the average per district change for the districts is shown. For example, in table C.81, 39 districts in the matched sample of 247 districts experienced decreases in E(H,M,50%) from 1968 to 1972 followed by increases from 1972 to 1976. The net average change over the entire 8 year period was an increase of .084.
